

# Linked List

# Lecture Question

## Task: Write reduce for our linked list

- Write a method in the `week8.linkedlist.LinkedListNode` class (from the examples repo) named `reduce` that:
  - Takes a function of type  $(A, A) \Rightarrow A$
  - Returns  $A$
  - Combines all the elements of the list into a single value by applying the provided function to all elements
    - You may assume the function is commutative  $f(a, b) == f(b, a)$
  - If the list has size 1, return that element without calling the provided function

**Testing:** In a package named "tests" create a class named "TestReduce" as a test suite that tests the functionality listed above (Do not test with an empty list/null)

### Example:

If head stores a reference to the `List(4, 6, 2)`

```
head.reduce((a: Int, b: Int) => a + b) == 12
```

# Recall - Array

- Sequential
  - One continuous block of memory
  - Random access based on memory address
    - $\text{address} = \text{first\_address} + (\text{element\_size} * \text{index})$
- Fixed Size
  - Since memory adjacent to the block may be used
  - Efficient when you know how many elements you'll need to store

# Array

Program Stack	
Main Frame	name:myArray, value:1503

Program Heap	
1503	myArray[0]
	myArray[1]
...	
	myArray[2]
...	
	myArray[3]
...	
[used by another program]	

- Arrays are stored on the heap
- Pointer to index 0 goes on the stack
- add index \* sizeofElement to 1503 to find each element
- This is called random access

# Recall - Linked List

- Sequential
  - Spread across memory
  - Each element knows the memory address of the next element
    - Follow the addresses to find each element
- Variable Size
  - Store new element anywhere in memory
  - New element stores address of the first element

# Linked List

Program Stack	
Main Frame	name:myList, value:506

- myList stores a list containing:  
[5,3,1]
- Last link stores null
  - We say the list is "null terminated"
  - When we read a value of null we know we reached the end of the list

Program Heap	
506	name:value, value:5
...	name:next, value:795

Program Heap	
795	name:value, value:3
...	name:next, value:416

Program Heap	
416	name:value, value:1
...	name:next, value:null

# Linked List

```
class LinkedListNode[A](var value: A, var next: LinkedListNode[A]) {  
  }  
}
```

```
var myList: LinkedListNode[Int] = new LinkedListNode[Int](1, null)  
myList = new LinkedListNode[Int](3, myList)  
myList = new LinkedListNode[Int](5, myList)
```

- We create our own linked list class by defining a node
  - A node represents one "link" in the list
- The list itself is a reference to the first/head node
- Note: This is a **mutable** list
  - You'll build immutable lists in CSE250

# Linked List

Program Stack	
Main Frame	name:myList, value: @416

```
class LinkedListNode[A](var value: A, var next: LinkedListNode[A]) {  
}
```

➔

```
var myList: LinkedListNode[Int] = new LinkedListNode[Int](1, null)  
myList = new LinkedListNode[Int](3, myList)  
myList = new LinkedListNode[Int](5, myList)
```

- Create a new variable to store the head (first node) of the list
- Create a new node with the value 1
- The list has size 1

Program Heap	
@416	name:value, value:1
...	name:next, value:null

# Linked List

Program Stack	
Main Frame	name:myList, value: @795

```
class LinkedListNode[A](var value: A, var next: LinkedListNode[A]) {  
}
```

➔

```
var myList: LinkedListNode[Int] = new LinkedListNode[Int](1, null)  
myList = new LinkedListNode[Int](3, myList)  
myList = new LinkedListNode[Int](5, myList)
```

- We prepend a new node to the list
- Create a new node with value 3
- The new node "refers" to the rest of the list
- The list has size 2

Program Heap	
@795	name:value, value:3
...	name:next, value: @416

Program Heap	
@416	name:value, value:1
...	name:next, value:null

# Linked List

Program Stack	
Main Frame	name:myList, value: @506

Program Heap	
@506	name:value, value:5
...	name:next, value: @795

Program Heap	
@795	name:value, value:3
...	name:next, value: @416

Program Heap	
@416	name:value, value:1
...	name:next, value:null

```
class LinkedListNode[A](var value: A, var next: LinkedListNode[A]) {  
}
```

```
var myList: LinkedListNode[Int] = new LinkedListNode[Int](1, null)  
myList = new LinkedListNode[Int](3, myList)  
→ myList = new LinkedListNode[Int](5, myList)
```

- Repeat the process to build a list of size 3
- Each node refers to the next node in the list
- The last node doesn't refer to anything (null) indicating the end of the list

# Linked List Algorithms

- We know the structure of a linked list
- How do we operate on these lists?
- We would like to:
  - Find the size of a list
  - Print all the elements of a list
  - Access elements by location
  - Add/remove elements
  - Find a specific value

# Size

- Navigate through the entire list until the next reference is null
- Count the number of nodes visited
- Could use a loop. Recursive example shown

```
def size(): Int = {  
    if(this.next == null){  
        1  
    }else{  
        this.next.size() + 1  
    }  
}
```

# To String

- Same as size, but accumulate the values as strings instead of counting the number of nodes
- Recursion makes it easier to manage our commas
  - ", " is only appended if it's not the last element

```
override def toString: String = {  
  if (this.next == null) {  
    this.value.toString  
  } else {  
    this.value.toString + ", " + this.next.toString  
  }  
}
```

# Debugger Demo

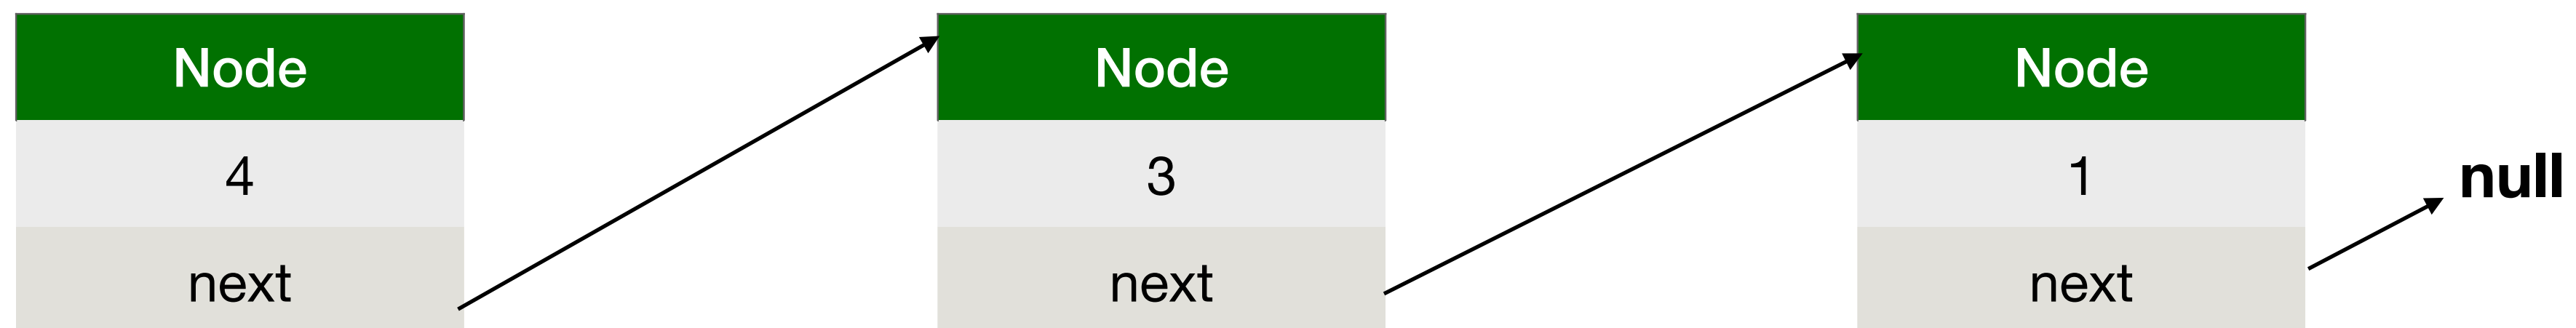

# Access Element by Location

- Simulates array access
- Take an "index" and advance through the list that many times
- MUCH slower than array access
  - Calls next n times -  $O(n)$  runtime
  - ex. `apply(4)` is the same as `this.next.next.next.next`

```
def apply(i: Int): LinkedListNode[A] = {  
  if (i == 0) {  
    this  
  } else {  
    this.next.apply(i - 1)  
  }  
}
```

# Add an Element

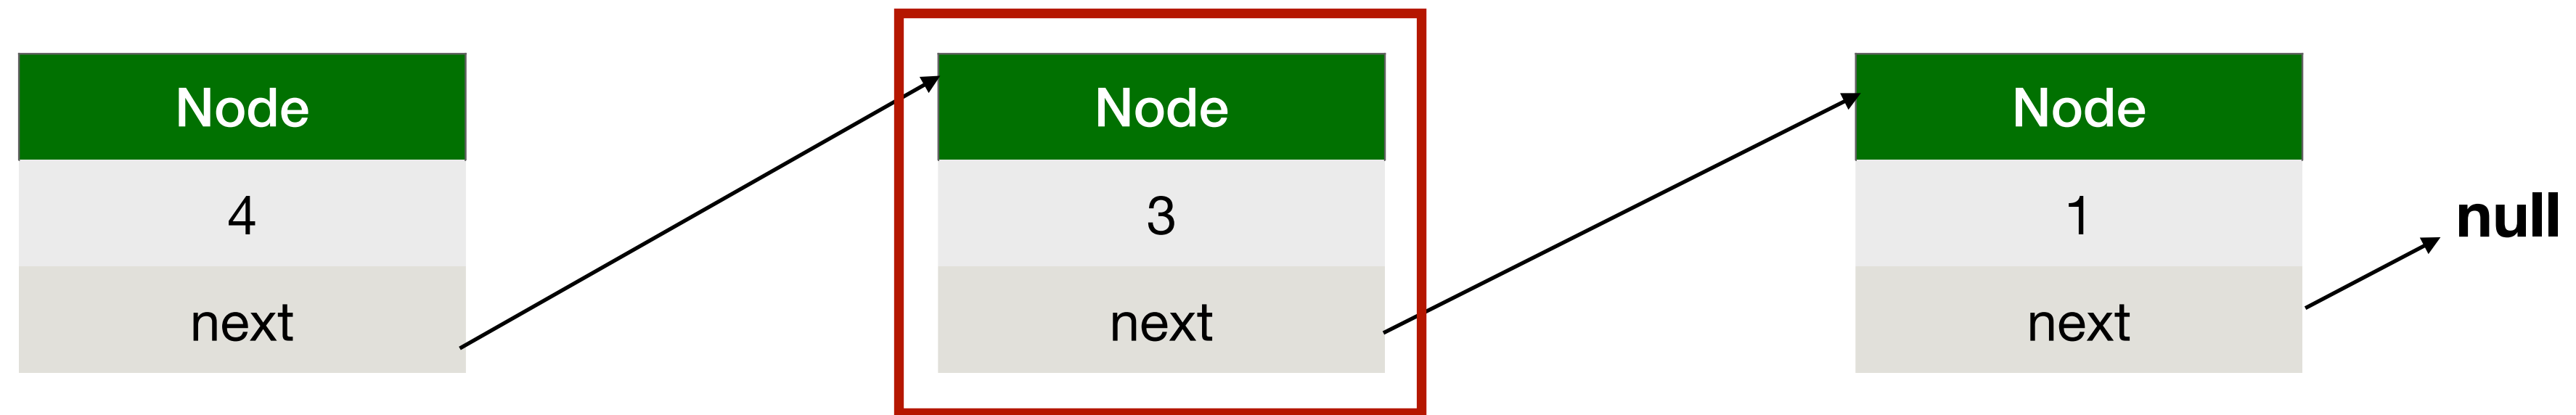

- To add an element we first need a reference to the node before the location of the new element
- Update the next reference of this node
- Want to add 2 in this list after 3

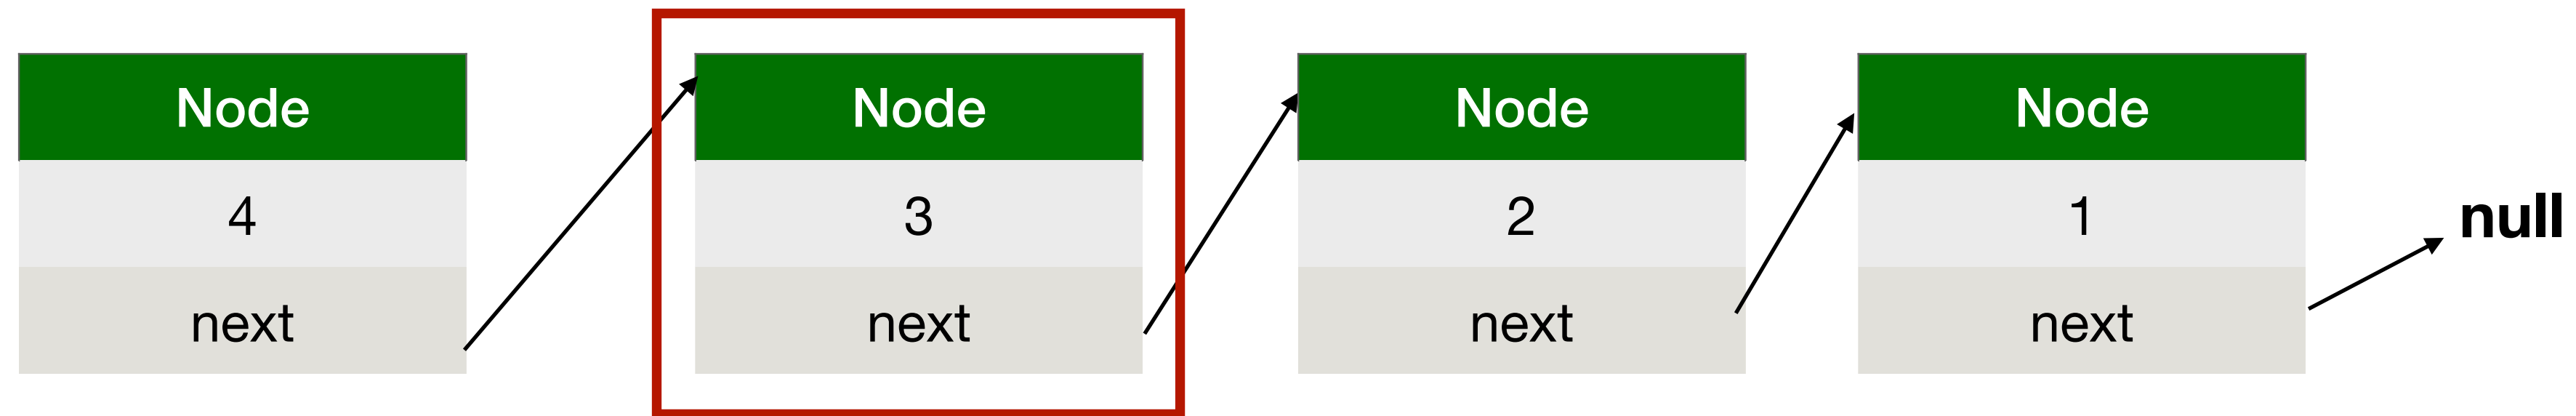

# Add an Element

- Need reference to the node containing 3

# Add an Element

- Need reference to the node containing 3
- Create the new node with next equal to this node's next
- This node's next is set to the new node

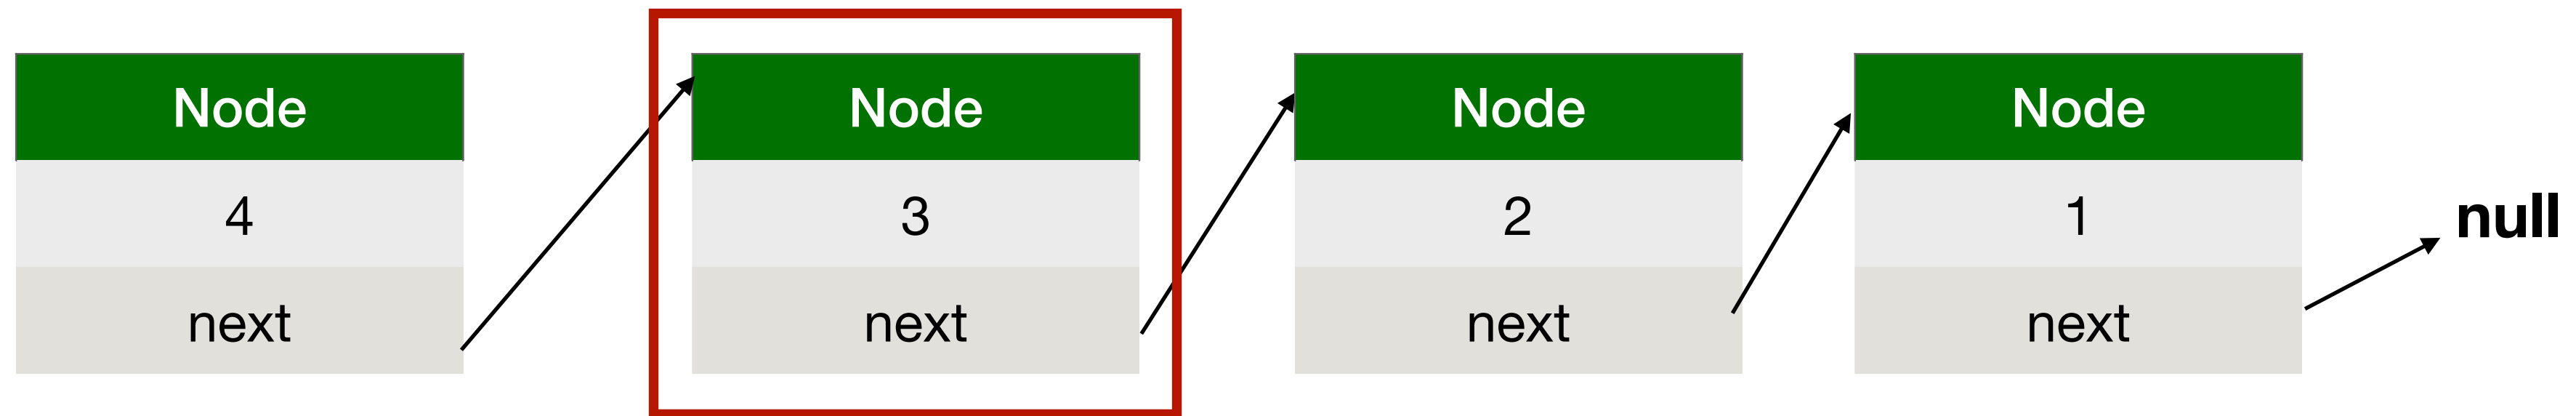

# Add an Element

- Need reference to the node containing 3
- Create the new node with next equal to this node's next
- This node's next is set to the new node

```
def insert(element: A): Unit = {  
    this.next = new LinkedListNode[A](element, this.next)  
}
```

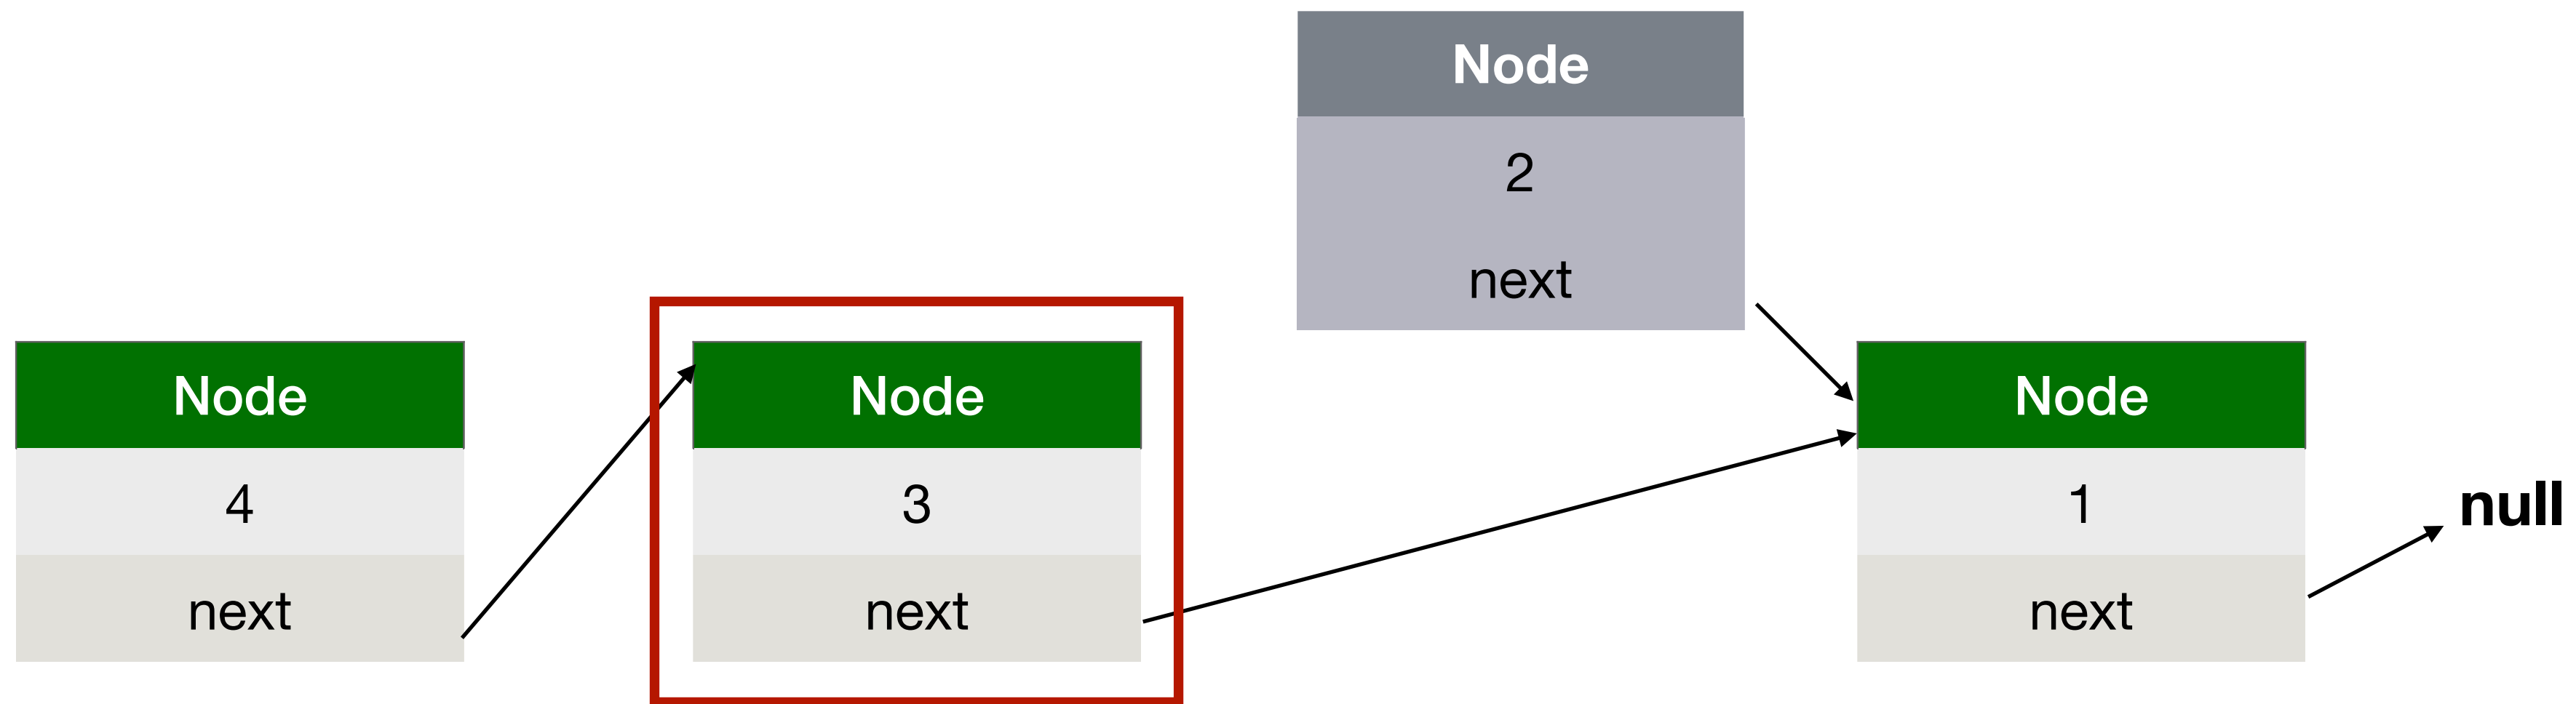

# Delete a Node

- Want to delete the node containing 2
- Need a reference to the previous node

# Delete a Node

- Update that node's next to bypass the deleted node
- Don't have to update deleted node
- The list no longer refers to this node

# Delete a Node

- Update that node's next to bypass the deleted node
- Don't have to update deleted node
- The list no longer refers to this node

```
def deleteAfter(): Unit = {  
    this.next = this.next.next  
}
```

# Find a Value

- Navigate through the list one node at a time
  - Check if the node contains the value
  - If it doesn't, move to the next node
  - If the end of the list is reached, the list does not contain the element

```
def find(toFind: A): LinkedListNode[A] = {  
  if (this.value == toFind) {  
    this  
  } else if (this.next == null) {  
    null  
  } else {  
    this.next.find(toFind)  
  }  
}
```

# Find - Recursion v. Iteration

```
def findIterative(toFind: A): LinkedListNode[A] = {  
    var node = this  
    while (node != null) {  
        if (node.value == toFind) {  
            return node  
        }  
        node = node.next  
    }  
    null  
}
```

```
def find(toFind: A): LinkedListNode[A] = {  
    if (this.value == toFind) {  
        this  
    } else if (this.next == null) {  
        null  
    } else {  
        this.next.find(toFind)  
    }  
}
```

# ForEach

- Call a function on each node of the list

```
def foreach(f: A => Unit): Unit = {  
    f(this.value)  
    if(this.next != null) {  
        this.next.foreach(f)  
    }  
}
```

# Map Usage

- Recall the map method for builtin List
- Used to transform every element in a list

```
val numbers: List[Int] = List(1, 2, 3, 4, 5, 6, 7, 8, 9, 10)
val numbersSquared: List[Int] = numbers.map((n: Int) => n * n)
println(numbersSquared)
```

**List(1, 4, 9, 16, 25, 36, 49, 64, 81, 100)**

# Map

- Apply a function to each element of the list
- Return a new list containing the return values of the function

```
def map(f: A => A): LinkedListNode[A] = {  
  val newValue = f(this.value)  
  if (this.next == null) {  
    new LinkedListNode[A](newValue, null)  
  } else {  
    new LinkedListNode[A](newValue, this.next.map(f))  
  }  
}
```

# Map - Change Type

- Can change the type of the returned list with a second type parameter
- A could be equal to B if you don't want to change the type
- Example: You want to divide a list of Ints by 2 and have to return a list of Doubles to avoid rounding

```
def map[B](f: A => B): LinkedListNode[B] = {  
  val newValue = f(this.value)  
  if (this.next == null) {  
    new LinkedListNode[B](newValue, null)  
  } else {  
    new LinkedListNode[B](newValue, this.next.map(f))  
  }  
}
```

# Lecture Question

## Task: Write reduce for our linked list

- Write a method in the `week8.linkedlist.LinkedListNode` class (from the examples repo) named `reduce` that:
  - Takes a function of type  $(A, A) \Rightarrow A$
  - Returns  $A$
  - Combines all the elements of the list into a single value by applying the provided function to all elements
    - You may assume the function is commutative
  - If the list has size 1, return that element without calling the provided function

**Testing:** In a package named "tests" create a class named "TestReduce" as a test suite that tests the functionality listed above (Do not test with an empty list/null)

### Example:

If head stores a reference to the `List(4, 6, 2)`

```
head.reduce((a: Int, b: Int) => a + b) == 12
```
