Unit Testing

Lecture Question

Function: In a package named "lecture" create an object named "FirstObject" with a method named "computeShippingCost" that takes a Double representing the weight of a package as a parameter and returns a Double representing the shipping cost of the package

The shipping cost is ($)5 + 0.25 for each pound over 30

Unit Testing: In a package named "tests" create a class/file named "UnitTesting" as a test suite that tests the computeShippingCost method

Testing

- How do you know if your code is correct?

- Submit to AutoLab?
  - Does not exist outside of class
  - Does not exist for your project

Recall

```scala
package example

object Conditional {

  def computeSize(input: Double): String = {
    val large: Double = 60.0
    val medium: Double = 30.0
    if (input >= large) {
      "large"
    } else if (input >= medium) {
      "medium"
    } else {
      "small"
    }
  }

}
```

- **How do we test this function to verify that it's correct?**

Recall

```scala
package example

object Conditional {

  def computeSize(input: Double): String = {
    val large: Double = 60.0
    val medium: Double = 30.0
    if (input >= large) {
      "large"
    } else if (input >= medium) {
      "medium"
    } else {
      "small"
    }
  }

  def main(args: Array[String]): Unit = {
    println(computeSize(70.0))
    println(computeSize(50.0))
    println(computeSize(10.0))
  }

}
```

- **Call the method from main**
- **Print the results**
- **Manually verify**

What About Large Projects?

- There may be 100's of files and 1000's of methods

- Any change in a function might break any code that calls that function

- Will you manually verify all that code for each change?

- Unit Testing

  - Automate testing

  - Provide structure to testing

Unit Testing

- Run a serious of tests on your code

- If the code is correct, all tests should pass

- If the code is incorrect, at least one test should fail

- A set of tests should test every possible error that could occur

Scala Unit Testing

```scala
package tests

import org.scalatest._
import example.Conditional

class TestComputeSize extends FunSuite {

  test("Doubles are checked for size in each category") {
    val largeDouble: Double = 70.0
    val mediumDouble: Double = 50.0
    val smallDouble: Double = 10.0

    assert(Conditional.computeSize(largeDouble) == "large", largeDouble)
    assert(Conditional.computeSize(mediumDouble) == "medium", mediumDouble)
    assert(Conditional.computeSize(smallDouble) == "small", smallDouble)
  }

}
```

Use Maven to download scalatest (see pom.xml on the course website)

Click Maven in the IntelliJ sidebar to interact with pom.xml

Scala Unit Testing

```scala
package tests

import org.scalatest._
import example.Conditional

class TestComputeSize extends FunSuite {

  test("Doubles are checked for size in each category") {
    val largeDouble: Double = 70.0
    val mediumDouble: Double = 50.0
    val smallDouble: Double = 10.0

    assert(Conditional.computeSize(largeDouble) == "large", largeDouble)
    assert(Conditional.computeSize(mediumDouble) == "medium", mediumDouble)
    assert(Conditional.computeSize(smallDouble) == "small", smallDouble)
  }

}
```

Import everything from the org.scalatest package

_ is a Scala wildcard

Scala Unit Testing

```scala
package tests

import org.scalatest._
import example.Conditional

class TestComputeSize extends FunSuite {

  test("Doubles are checked for size in each category") {
    val largeDouble: Double = 70.0
    val mediumDouble: Double = 50.0
    val smallDouble: Double = 10.0

    assert(Conditional.computeSize(largeDouble) == "large", largeDouble)
    assert(Conditional.computeSize(mediumDouble) == "medium", mediumDouble)
    assert(Conditional.computeSize(smallDouble) == "small", smallDouble)
  }

}
```

Create a new class of type FunSuite (Function Suite)

*More details on this syntax next week. This is inheritance

Scala Unit Testing

```scala
package tests

import org.scalatest._
import example.Conditional

class TestComputeSize extends FunSuite {

  test("Doubles are checked for size in each category") {
    val largeDouble: Double = 70.0
    val mediumDouble: Double = 50.0
    val smallDouble: Double = 10.0

    assert(Conditional.computeSize(largeDouble) == "large", largeDouble)
    assert(Conditional.computeSize(mediumDouble) == "medium", mediumDouble)
    assert(Conditional.computeSize(smallDouble) == "small", smallDouble)
  }

}
```

Create a new test that will be executed when this file is ran

No main method

FunSuite controls execution instead of main

Scala Unit Testing

```scala
package tests

import org.scalatest._
import example.Conditional

class TestComputeSize extends FunSuite {

  test("Doubles are checked for size in each category") {
    val largeDouble: Double = 70.0
    val mediumDouble: Double = 50.0
    val smallDouble: Double = 10.0

    assert(Conditional.computeSize(largeDouble) == "large", largeDouble)
    assert(Conditional.computeSize(mediumDouble) == "medium", mediumDouble)
    assert(Conditional.computeSize(smallDouble) == "small", smallDouble)
  }

}
```

Call assert to test values

First argument is a boolean that must be true for the test to pass
-Should return false if the code is not correct
Second argument is optional. Is printed if the test fails

Scala Unit Testing

```scala
package tests

import org.scalatest._
import example.Conditional

class TestComputeSize extends FunSuite {

  test("Doubles are checked for size in each category") {
    val largeDouble: Double = 70.0
    val mediumDouble: Double = 50.0
    val smallDouble: Double = 10.0

    assert(Conditional.computeSize(largeDouble) == "large", largeDouble)
    assert(Conditional.computeSize(mediumDouble) == "medium", mediumDouble)
    assert(Conditional.computeSize(smallDouble) == "small", smallDouble)
  }

}
```

This class tests if the inputs 70.0, 50.0, and 10.0 return "large", "medium", and "small" respectively

Is this enough testing?

Correct Solution

```scala
package example

object Conditional {

  def computeSize(input: Double): String = {
    val large: Double = 60.0
    val medium: Double = 30.0
    if (input >= large) {
      "large"
    } else if (input >= medium) {
      "medium"
    } else {
      "small"
    }
  }

}
```

Incorrect Solution -Passes the tests-

```scala
package example

object Conditional {

  def computeSize(input: Double): String = {
    val large: Double = 65.0
    val medium: Double = 20.0
    if (input >= large) {
      "large"
    } else if (input >= medium) {
      "medium"
    } else {
      "small"
    }
  }

}
```

Scala Unit Testing

```scala
package tests

import org.scalatest._
import example.Conditional

class TestComputeSize extends FunSuite {

  test("Size boundaries are checked"){
    val largeDouble: Double = 60.0
    val mediumDoubleUpperBound: Double = 59.99
    val mediumDoubleLowerBound: Double = 30.0
    val smallDouble: Double = 29.99

    assert(Conditional.computeSize(largeDouble) == "large", largeDouble)
    assert(Conditional.computeSize(mediumDoubleUpperBound) == "medium", mediumDoubleUpperBound)
    assert(Conditional.computeSize(mediumDoubleLowerBound) == "medium", mediumDoubleLowerBound)
    assert(Conditional.computeSize(smallDouble) == "small", smallDouble)
  }

}
```

Check the boundaries for more accurate testing

Is this enough testing?

Scala Unit Testing

```scala
package tests

import org.scalatest._
import example.Conditional

class TestComputeSize extends FunSuite {

  test("Size boundaries are checked"){
    val largeDouble: Double = 60.0
    val mediumDoubleUpperBound: Double = 59.99
    val mediumDoubleLowerBound: Double = 30.0
    val smallDouble: Double = 29.99

    assert(Conditional.computeSize(largeDouble) == "large", largeDouble)
    assert(Conditional.computeSize(mediumDoubleUpperBound) == "medium", mediumDoubleUpperBound)
    assert(Conditional.computeSize(mediumDoubleLowerBound) == "medium", mediumDoubleLowerBound)
    assert(Conditional.computeSize(smallDouble) == "small", smallDouble)
  }

}
```

Check the boundaries for more accurate testing

Is this enough testing?

We could reasonable stop here.. but we could do more thorough testing

Scala Unit Testing

```scala
package tests

import org.scalatest._
import example.Conditional

class TestComputeSize extends FunSuite {

  test("Use many test cases for each category"){
    // notice largeDoubles must be declared with var we change its value
    var largeDoubles: List[Double] = List(60.0, 60.01, 70.0, 90.0, 1000.0)
    val mediumDoubles: List[Double] = List(59.9, 30.0, 30.01, 40.0, 50.0)
    val smallDoubles: List[Double] = List(29.99, 20.0, 10.0, 0.0, -100.0, -10000.0)

    largeDoubles = largeDoubles :+ 10000.0 // Example of adding an element to a List

    for(largeDouble <- largeDoubles){
      assert(Conditional.computeSize(largeDouble) == "large", largeDouble)
    }
    for(mediumDouble <- mediumDoubles){
      assert(Conditional.computeSize(mediumDouble) == "medium", mediumDouble)
    }
    for(smallDouble <- smallDoubles){
      assert(Conditional.computeSize(smallDouble) == "small", smallDouble)
    }

  }

}
```

Use data structures to run many test cases

Unit Testing Objectives

- Each homework, and other places in the course, will have objectives that require thorough testing

- When these objectives are graded, your test suite is ran:

  - Against your solution

  - Against a correct solution stored o the server

  - Against a variety of incorrect solution stored on the server

- Your test suite must pass on both your solution and the correct solution to earn any points

- If both yours and the correct solution are passed, you earn points for each incorrect solution that your test suite fails

- Thorough testing should be able to distinguish between all correct and incorrect code

  - ie. If your code contains errors, proper tests should notify you that there is an error so you don't release buggy software

Maven: Dependency Management

- To run this testing code, we used an external library named Scalatest

  - Scalatest does not come with Scala

  - We must download it before running tests

- To manage external libraries, we'll use Maven

  - List all dependancies (libraries) in a file named pom.xml

  - Save pom.xml in the root directory of your project

  - Use Maven to download all dependancies

- The pom.xml is similar to the requirements.txt file we used in Python

Maven Demo

And fixing Scala/JDK Versions

Lecture Question

Function: In a package named "lecture" create an object named "FirstObject" with a method named "computeShippingCost" that takes a Double representing the weight of a package as a parameter and returns a Double representing the shipping cost of the package

The shipping cost is ($)5 + 0.25 for each pound over 30

Unit Testing: In a package named "tests" create a class/file named "UnitTesting" as a test suite that tests the computeShippingCost method

rounding_weight

```scala
def computeShippingCost(weight: Double): Double = {
  if (weight < 3.0) {
    5.0
  } else {
    5.0 + (Math.round(weight) - 30.0) * 0.25
  }
}
```

always_over_thirty

```scala
def computeShippingCost(weight: Double): Double = {
  5.0 + (weight - 30.0) * 0.25
}
```

boundary_overweight

```scala
def computeShippingCost(weight: Double): Double = {
  if (weight < 33.0) {
    5.0
  } else {
    5.0 + (weight - 33.0) * 0.25
  }
}
```

light_employee_discount

```scala
def computeShippingCost(weight: Double): Double = {
  if (weight < 30.0) {
    4.0
  } else {
    5.0 + (weight - 30.0) * 0.25
  }
}
```

always_under_thirty

```scala
def computeShippingCost(weight: Double): Double = {
  5.0
}
```
