Linked List

Recall - Array

- Sequential

  - One continuous block of memory

  - Random access based on memory address

    - address = first_address + (element_size * index)

- Fixed Size

  - Since memory adjacent to the block may be used

  - Efficient when you know how many elements you'll need to store

Array

Program Stack	
Main Frame	name:myArray, value:1503

Program Heap	
1503	myArray[0]
...	myArray[1]
...	myArray[2]
...	myArray[3]
[used by another program]	

- Arrays are stored on the heap

- Pointer to index 0 goes on the stack

- add index * sizeOfElement to 1503 to find each element

  - This is called random access

Recall - Linked List

- Sequential

  - Spread across memory

  - Each element knows the memory address of the next element

    - Follow the addresses to find each element

- Variable Size

  - Store new element anywhere in memory

  - Add store the memory address in the last element

    - or new element stores address of first element

Linked List

Program Stack	
Main Frame	name:myList, value:506

Program Heap	
506	name:value, value:5
...	name:next, value:795

Program Heap	
795	name:value, value:3
...	name:next, value:416

Program Heap	
416	name:value, value:1
...	name:next, value:null

- myList stores a list containing: [5,3,1]

- Last link stores null

  - We say the list is "null terminated"

  - When we read a value of null we know we reached the end of the list

Linked List

Program Stack	
Main Frame	name:myList, value:506

Program Heap	
506	name:value, value:5
...	name:next, value:795

Program Heap	
795	name:value, value:3
...	name:next, value:416

Program Heap	
416	name:value, value:1
...	name:next, value:null

```
class LinkedListNode[A](var value: A, var next: LinkedListNode[A]) {

}
```

```
var myList: LinkedListNode[Int] = new LinkedListNode[Int](1, null)
myList = new LinkedListNode[Int](3, myList)
myList = new LinkedListNode[Int](5, myList)
```

- We create our own linked list class by defining a node

  - A node represents one "link" in the list

- The list itself is a reference to the first/head node

Lecture Question

Task: Write a prepend method for our linked list

- Write a method in the datastructures.LinkedListNode class (from the repo) named prepend that:

  - Takes a value of type A as its parameter

  - Prepends the input to the front of this list (assume the method is called on the head node)

  - Returns a reference to the new head of the list
